Tissue samples are routinely removed from patients during a variety of surgical and other procedures to aid in the diagnosis and treatment of a variety of diseases. For example, when biopsy tissue samples are removed for histopathological evaluation, a diagnosis of malignancy or benignancy of a lesion is made based on the appearance of the biopsy tissue sample. In other applications, a test sample may be obtained from biopsied tissue for testing or analysis. In any of these types of applications, a biopsy is performed by inserting a biopsy needle into the patient through a small incision or a natural opening of the patient and into the tissue to be sampled. The biopsy needle includes a lumen into which the tissue sample is drawn when the needle is withdrawn from the patient. There are several known methods of obtaining biopsy tissue samples. For example, for removal of cancerous cells or tissue, an open biopsy is performed where the natural tissue is cut out with a scalpel and then sent to a lab to be analyzed. Another method employs a core biopsy, which involves removing a core of tissue through a needle for histopathological examination. In order to facilitate visualization of the tissue being removed, the needle used to remove the tissue is typically vibrated or an aspiration line is used to remove the tissue as the tissue is being aspirated through the lumen of the needle. In an effort to reduce the size of the incision required to perform a biopsy and thereby reduce the discomfort to the patient, a biopsy needle having a small diameter is desirable. Smaller needles, however, are more prone to clogging and damage the tissue sample in the process of obtaining the tissue sample. A minimally invasive biopsy procedure typically involves mounting an open biopsy forceps on the distal end of the biopsy needle to facilitate tissue collection. b7e8fd5c8
